CpRu complexes are interesting alternatives to copper and dirhodium species for the metal-catalyzed decomposition of diazo compounds.^[1] In this context, it has been shown that combinations of $[\text{CpRu}(\text{CH}_3\text{CN})_3]\text{[PF}_6]$ and diimine ligands react catalytically with α -diazo- β -ketoesters and allow subsequent condensation, OH and 1,3-CH insertion reactions.^[2] Recently, using this catalytic combination, new dioxene motifs were synthetized by enantiospecific syn-opening of epoxides.^[3]

In a new development that uses electron-poor pyridines and quinolines as substrates, the direct formation of original oxazine moieties **1** is described. Reactions proceed by tandem (double) additions of carbenes and a dearomatization of the azaaromatics. Such a process occurs primarily via ruthenium cyclopentadienyl catalysis since, under Rh(II)-mediated reactions, pyridinium ylides **2** are the major adducts.^[4] Mechanistic insights will be also presented.
